

ABSTRACT OF THE DISCLOSURE

A method and system for a communication scheme between a plurality of applications over heterogeneous networks. The method and system include sending an alias identifier via a first application, an alias mechanism resolves and/or translated the alias identifier using a data storage medium. The data storage medium can be accessed via a management interface. The alias identifier is associated with a command and an application layer address. The alias mechanism then can execute the command to provide a communication arrangement. Access to the data storage medium could further require an access code from an entity, user, device and/or application.
